Pathways to Black and White

• INTRODUCTION
• KODAK BLACK-AND-WHITE FILMS
• KODAK BLACK-AND-WHITE PAPERS

INTRODUCTION
The pathway you choose to produce a finished black-and-white image will depend on your original and your specific application. The most fundamental path is to make a positive black-and-white reflection print from a black-and-white negative. The following shows a wide variety of ways to arrive at your final image.

KODAK BLACK-AND-WHITE FILMS
General picture-taking continuous-tone films, such as KODAK PROFESSIONAL TRI-X 400 Film or KODAK PROFESSIONAL T-MAX Films, are usually used to make black-and-white enlargements on conventional black-and-white papers. However, you can also use some films to make positive slides, copy negatives or display transparencies in a range of contrasts.

Copy negatives are usually negatives made by photographing black-and-white reflection prints. For best results, use KODAK PROFESSIONAL T-MAX 100 Film.

Kodak also makes a variety of continuous-tone black-and-white chemicals for processing these films.

For special-purpose applications, you may have to use a conventional developer in a non-conventional way or use a special-purpose developer. This applies especially when you need to alter the contrast of the original. You may want to experiment with some special-purpose developers such as KODAK Developer D-19 and the KODAK T-MAX 100 Direct Positive Film Developing Outfit.

KODAK BLACK-AND-WHITE PAPERS
Kodak papers are either fiber-base or resin-coated (RC), and available in graded- or selective-contrast types. Generally, their most common function is to make black-and-white reflection positives (prints) from black-and-white film negatives.

Fiber-Base Papers. These papers are made from a chemically pure paper base coated with a bright white barium sulfate layer over which the emulsion is coated. This base is highly absorptive and requires relatively long wash times to remove processing chemicals.

Resin-Coated Papers. These papers are coated with a waterproof resin on both sides, which prevents processing chemicals from penetrating the paper base. Therefore, processing and washing times are much shorter.

Graded Papers. You can obtain levels of contrast with these papers by selecting the appropriate grade number. A grade 2 paper is “normal.” For higher contrast, use grade 3, 4, or 5. For lower contrast, use grade 0 or 1. Not all contrast grades are available in all paper types. Graded papers are primarily used in applications such as portraiture, where negative 4 quality and contrast are controlled by standard lighting and processing conditions.

Selective-Contrast Papers. You can control contrast levels with these papers by using filters, such as KODAK POLYMAX Filters*, to alter the blue/green ratio of the exposing light. POLYMAX Filters are available in kits and 90 and 150 mm square sets in grades –1 through 5+ that produce 12 contrast levels ranging from very low to extremely high. In many cases, using these filters with selective-contrast papers will produce contrast ranges much greater than those available with graded papers.

Special-Purpose Papers. To make black-and-white prints from color negatives, you can use KODAK PANALURE SELECT RC Paper or KODAK PROFESSIONAL PORTRA Black & White Paper. PANALURE SELECT RC Paper is processed in conventional black-and-white chemicals, but KODAK PROFESSIONAL PORTRA Black & White Paper requires KODAK EKTACOLOR Chemicals for Process RA-4. PORTRA Black & White Paper is designed for the convenience of finishers who want to make black-and-white prints without having to maintain a separate black-and-white process.

* The filter kit, filter sets, and filter upgrade sets are now distributed by Tiffen Co. L.L.C. In the U.S. call 800-368-6257 or view their website at www.tiffen.com.

*Color-Sensitivity Classifications—

Blue-sensitive films are sensitive only to ultraviolet radiation and blue light. You can use a safelight with a KODAK Safelight Filter, Nos. OA (greenish yellow), OC (light amber), or 1A (light red) during handling and processing. These safelights provide fairly good light level for darkroom work.

Orthochromatic films are sensitive to ultraviolet radiation and blue and green light. You can use KODAK 1A Safelight Filter (light red) during handling and processing. This filter also permits a fairly good light level in the darkroom.

Panchromatic films are sensitive to all colors of light as well as ultraviolet radiation. They produce gray-tone rendering of subject colors that approximate their visual brightness, and can provide a variety of gray-tone renderings when you expose them with filters. No safelight is recommended, although you can use a green KODAK 3 Safelight Filter (dark green) with black-and-white film on KODAK PROFESSIONAL T-MAX Films for a few seconds during processing. This safelight transmits only enough light to determine contours, not detail.

Extended red films are panchromatic films with extended red sensitivity. Do not use a safelight; handle these films in total darkness.

†Note: This list includes the Kodak developers most commonly used for processing these films or papers. See the developer, film, or paper instructions for processing and special agitation procedures.

§KODAK T-MAX 100 Direct Positive Film Developing Outfit is for producing continuous-tone positive black-and-white slides from KODAK PROFESSIONAL T-MAX 100 Film.

Surface (texture and sheen)
- **D**—Smooth, fine lustre
- **E**—Fine-grained, lustre
- **F**—Smooth, glossy
- **N**—Smooth, semi-matt

Base Weight
- **SW**—Single weight
- **DW**—Double weight
- **MW**—Medium weight
**KEY—**

**Continuous Tone** An image that exhibits a smooth gradation of tones or shades of gray from light to dark. Continuous-tone images may be positive or negative, or have high or low contrast.

**Contrast** The difference in brightness between the lightest and darkest tones of an image or scene. Images or scenes that exhibit very light to very dark tones with few intermediate tones are called “high contrast.” “Low contrast” images are usually characterized by a short range of tones—such as middle gray to dark gray, without any black or white.

**Copy Negative** A negative made from a positive print or transparency, for the purpose of making additional prints by conventional photographic means. Can also be used to correct defects or adjust the contrast of an original image to make subsequent printing easier, such as when hundreds of prints must be made from a negative that is difficult to print.

**Duplicate Negative** A negative made from a negative that matches or enhances the contrast and characteristics of the original as closely as possible. Often made when an original is too valuable to be subjected to frequent handling. Usually made from direct-positive materials or by the “interpositive” method.

**Internegative** Usually a copy negative made from a transparency or color print.

**Interpositive** A specific type of transparency, or film positive, that is the first step in a two-step negative duplication. A negative is “printed” onto a negative-working film that reverses the tonal values. The resulting film positive is then “printed” onto negative film, which restores the tonal relationships of the original negative. Requires rigorous control to maintain the exact contrast of the original through the steps.

**Line or Line Copy** An image exhibiting only solid blocks or lines of tone with no tonal gradations, such as text on a page. These images may be positive or negative, and usually have very high contrast.
**Mask** An intermediate image made from a negative or transparency for the purpose of altering the characteristics of a negative or transparency. Once made, the mask is sandwiched “in register” with the negative or transparency to increase or reduce contrast.

**Negative** A developed photographic image in which the tonal relationships of the original scene are reversed—light tones are recorded as dark and dark tones as light. The “negative” is then “printed” to restore a normal, or positive image.

**Negative Working** A photographic material that reverses the tones in an image. Conventional photographic materials are negative working because light-sensitive compounds usually darken or increase in visual density with increasing exposure to light. Therefore, a negative-working camera film reverses the tones of the original scene, and a companion negative-working print material reverses the tones again, back to their “normal” or positive relationship.

**Positive** A photographic image with similar light-to-dark tonal values as those in the original scene. The ultimate result of the photographic process is usually a positive image. If it is on paper or similar opaque support, it’s commonly called a “print.” If the positive image is on a clear support, such as glass or film, it’s commonly called a “transparency” or “slide.”

**Positive Working** A photographic material that retains the tonal value of the original scene (rather than reversing them). Light areas in the original create light areas in the camera film, etc. Also called “direct positive” because it does not require a separate printing (interpositive) step as negative-working films do.

**Print** In photography, a print is usually a positive image on an opaque support, such as fiber-base or resin-coated paper. The image is viewed by reflecting light from the print surface.

**Transparency** A positive image on a transparent or translucent support, such as film. Viewed by directing light through the support. Also called “film positive.”
